CS187

Project 4: Semantic Interpretation – Question Answering

The goal of semantic parsing is to convert natural language utterances to a meaning representation such as a *logical form* expression or a *SQL query*. In the previous project segment, you built a parsing system to reconstruct parse trees from the natural-language queries in the ATIS dataset. However, that only solves an intermediary task, not the end-user task of obtaining answers to the queries.

In this final project segment, you will go further, building a semantic parsing system to convert English queries to SQL queries, so that by consulting a database you will be able to answer those questions. You will implement both a rule-based approach and an end-to-end sequence-to-sequence (seq2seq) approach. Both algorithms come with their pros and cons, and by the end of this segment you should have a basic understanding of the characteristics of the two approaches.

Goals

- 1. Build a semantic parsing algorithm to convert text to SQL queries based on the syntactic parse trees from the last project.
- 2. Build an attention-based end-to-end seg2seg system to convert text to SQL.
- 3. Improve the attention-based end-to-end seq2seq system with self-attention to convert text to SQL.
- 4. Discuss the pros and cons of the rule-based system and the end-to-end system.
- 5. (Optional) Use the state-of-the-art pretrained transformers for text-to-SQL conversion.

This will be an extremely challenging project, so we recommend that you start early.

Setup

```

```

Semantically augmented grammars

In the first part of this project segment, you'll be implementing a rule-based system for semantic interpretation of sentences. Before jumping into using such a system on the ATIS dataset – we'll get to that soon enough – let's first work with some trivial examples to get things going.

The fundamental idea of rule-based semantic interpretation is the rule of compositionality, that the meaning of a constituent is a function of the meanings of its immediate subconstituents and the syntactic rule that combined them. This leads to an infrastructure for specifying semantic

interpretation in which each syntactic rule in a grammar (in our case, a context-free grammar) is associated with a semantic rule that applies to the meanings associated with the elements on the right-hand side of the rule.

Example: arithmetic expressions

As a first example, let's consider an augmented grammar for arithmetic expressions, familiar from lab 3-1. We again use the function xform.parse_augmented_grammar to parse the augmented grammar. You can read more about it in the file scripts/transform.py.

```
In [46]: arithmetic grammar, arithmetic augmentations = xform.parse augmented gramma
              ## Sample grammar for arithmetic expressions
              S -> NUM
                                                       : lambda Num: Num
                 S OP S
                                                       : lambda S1, Op, S2: Op(S1, S2)
              OP -> ADD
                                                       : lambda Op: Op
                   SUB
                   MULT
                  DIV
              NUM -> 'zero'
                                                       : lambda: 0
                     'one'
                                                       : lambda: 1
                      'two'
                                                       : lambda: 2
                     'three'
                                                       : lambda: 3
                      'four'
                                                       : lambda: 4
                      'five'
                                                       : lambda: 5
                      'six'
                                                       : lambda: 6
                      'seven'
                                                       : lambda: 7
                      'eight'
                                                       : lambda: 8
                      'nine'
                                                       : lambda: 9
                      'ten'
                                                       : lambda: 10
              ADD -> 'plus' | 'added' 'to' : lambda: lambda x, y: x + y
              SUB -> 'minus' : lambda: lambda x, y: x - y MULT -> 'times' | 'multiplied' 'by' : lambda: lambda x, y: x * y
              DIV -> 'divided' 'by'
                                                     : lambda: lambda x, y: x / y
```

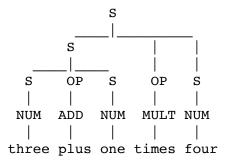

Recall that in this grammar specification format, rules that are not explicitly provided with an augmentation (like all the OP rules after the first OP -> ADD) are associated with the textually most recent one (lambda Op: Op).

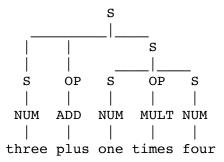

The parse_augmented_grammar function returns both an NLTK grammar and a dictionary that maps from productions in the grammar to their associated augmentations. Let's examine the returned grammar.

```
In [47]: for production in arithmetic grammar.productions():
           print(f"{repr(production):25}
                                              {arithmetic augmentations[production]}"

         MULT -> 'times'
                                        <function <lambda> at 0x7ffb05212790>
         MULT -> 'multiplied' 'by'
                                        <function <lambda> at 0x7ffb05212820>
         DIV -> 'divided' 'by'
                                        <function <lambda> at 0x7ffb052128b0>
```

We can parse with the grammar using one of the built-in NLTK parsers.

```
In [48]: arithmetic_parser = nltk.parse.BottomUpChartParser(arithmetic_grammar)
    parses = [p for p in arithmetic_parser.parse('three plus one times four'.sp
    for parse in parses:
        parse.pretty_print()
```

Now let's turn to the augmentations. They can be arbitrary Python functions applied to the semantic representations associated with the right-hand-side nonterminals, returning the semantic representation of the left-hand side. To interpret the semantic representation of the entire sentence (at the root of the parse tree), we can use the following pseudo-code:

```
to interpret a tree:
   interpret each of the nonterminal-rooted subtrees
   find the augmentation associated with the root production of the
   tree
```

(it should be a function of as many arguments as there are nont erminals on the right-hand side)

return the result of applying the augmentation to the subtree values

(The base case of this recursion occurs when the number of nonterminal-rooted subtrees is zero, that is, a rule all of whose right-hand side elements are terminals.)

Suppose we had such a function, call it interpret. How would it operate on, for instance, the tree (S (S (NUM three)) (OP (ADD plus)) (S (NUM one)))?

```
interpret (S (S (NUM three)) (OP (ADD plus)) (S (NUM one)))
    |->interpret (S (NUM three))
           |->interpret (NUM three)
                  |->(no subconstituents to evaluate)
                  |->apply the augmentation for the rule NUM -> thr
ee to the empty set of values
                          (lambda: 3) () ==> 3
                  \==> 3
           |->apply the augmentation for the rule S -> NUM to the v
alue 3
                  (lambda NUM: NUM)(3) ==> 3
           \==> 3
    |->interpret (OP (ADD plus))
           | . . .
           => lambda x, y: x + y
    ->interpret (S (NUM one))
           | . . .
           \==> 1
    |->apply the augmentation for the rule S -> S OP S to the value
s 3, (lambda x, y: x + y), and 1
           (lambda S1, Op, S2: Op(S1, S2))(3, (lambda x, y: x + y),
1) ==> 4
    \==> 4
```

Thus, the string "three plus one" is semantically interpreted as the value 4.

We provide the interpret function to carry out this recursive process, copied over from lab 4-2:

Now we should be able to evaluate the arithmetic example from above.

```
In [50]: interpret(parses[0], arithmetic_augmentations)
Out[50]: 16
```

And we can even write a function that parses and interprets a string. We'll have it evaluate each of the possible parses and print the results.

```
In [51]: def parse_and_interpret(string, grammar, augmentations):
    parser = nltk.parse.BottomUpChartParser(grammar)
    parses = parser.parse(string.split())
    for parse in parses:
        parse.pretty_print()
        print(parse, "==>", interpret(parse, augmentations))
```

In [52]: parse_and_interpret("three plus one times four", arithmetic_grammar, arithm

```
S
       S
  S
       OP
            S
                  OP
                       S
 NUM
           NUM
                 MULT NUM
      ADD
three plus one times four
(S
  (S (S (NUM three)) (OP (ADD plus)) (S (NUM one)))
  (OP (MULT times))
  (S (NUM four))) ==> 16
            S
                  S
  S
       OP
            S
                  OP
                       S
 NUM
      ADD
           NUM
                 MULT NUM
three plus one times four
(S
  (S (NUM three))
  (OP (ADD plus))
  (S (S (NUM one)) (OP (MULT times)) (S (NUM four)))) ==> 7
```

Since the string is syntactically ambiguous according to the grammar, it is semantically ambiguous as well.

Some grammar specification conveniences

Before going on, it will be useful to have a few more conveniences in writing augmentations for rules. First, since the augmentations are arbitrary Python expressions, they can be built from and make use of other functions. For instance, you'll notice that many of the augmentations at the leaves of the tree took no arguments and returned a constant. We can define a function constant that returns a function that ignores its arguments and returns a particular value.

```
In [53]: def constant(value):
    """Return `value`, ignoring any arguments"""
    return lambda *args: value
```

Similarly, several of the augmentations are functions that just return their first argument. Again, we can define a generic form first of such a function:

We can now rewrite the grammar above to take advantage of these shortcuts.

In the call to parse_augmented_grammar below, we pass in the global environment, extracted via a globals() function call, via the named argument globals. This allows the parse_augmented_grammar function to make use of the global bindings for constant, first, and the like when evaluating the augmentation expressions to their values. You can check out the code in transform.py to see how the passed in globals bindings are used. To help understand what's going on, see what happens if you don't include the globals=globals().

```
In [55]: arithmetic grammar 2, arithmetic augmentations 2 = xform.parse augmented gr
             ## Sample grammar for arithmetic expressions
             S -> NUM
                S OP S
                                                    : lambda S1, Op, S2: Op(S1, S2)
             OP -> ADD
                                                    : first
                SUB
                 MULT
                DIV
             NUM -> 'zero'
                                                    : constant(0)
                    'one'
                                                    : constant(1)
                    'two'
                                                    : constant(2)
                    'three'
                                                    : constant(3)
                    'four'
                                                    : constant(4)
                    'five'
                                                    : constant(5)
                    'six'
                                                    : constant(6)
                    'seven'
                                                    : constant(7)
                    'eight'
                                                    : constant(8)
                    'nine'
                                                    : constant(9)
                    'ten'
                                                    : constant(10)
             ADD -> 'plus' | 'added' 'to' : constant(lambda x, y: x + y)
             SUB -> 'minus'
                                                    : constant(lambda x, y: x - y)
             MULT -> 'times' | 'multiplied' 'by' : constant(lambda x, y: x * y)
             DIV -> 'divided' 'by'
                                                  : constant(lambda x, y: x / y)
             globals=globals())
```

Finally, it might make our lives easier to write a template of augmentations whose instantiation depends on the right-hand side of the rule.

We use a reserved keyword _RHS to denote the right-hand side of the syntactic rule, which will be replaced by a **list** of the right-hand-side strings. For example, an augmentation numeric_template(_RHS) would be as if written as numeric_template(['zero']) when the rule is NUM -> 'zero', and numeric_template(['one']) when the rule is NUM -> 'one'. The details of how this works can be found at scripts/transform.py (https://github.com/nlp-course/data/blob/master/scripts/trees/transform.py).

This would allow us to use a single template function, for example,

and then further simplify the grammar specification:

```
In [57]: arithmetic grammar 3, arithmetic augmentations 3 = xform.parse augmented gr
             ## Sample grammar for arithmetic expressions
             S -> NUM
                                                   : first
               S OP S
                                                   : lambda S1, Op, S2: Op(S1, S2)
             OP -> ADD
                                                   : first
                SUB
                 \mathtt{MULT}
                DIV
             NUM -> 'zero'
                             'one'
                                       'two'
                                                : numeric template( RHS)
                              'four'
                    'three'
                                      | 'five'
                              'seven' | 'eight'
                    'six'
                             'ten'
                    'nine'
             ADD -> 'plus' | 'added' 'to' : constant(lambda x, y: x + y)
             SUB -> 'minus'
                                                  : constant(lambda x, y: x - y)
             MULT -> 'times' | 'multiplied' 'by' : constant(lambda x, y: x * y)
             DIV -> 'divided' 'by'
                                                   : constant(lambda x, y: x / y)
             """,
             globals=globals())
```

In [58]: parse and interpret("six divided by three", arithmetic grammar 3, arithmeti

Example: Green Eggs and Ham revisited

This stuff is tricky, so it's useful to see more examples before jumping in the deep end. In this simple GEaH fragment grammar, we use a larger set of auxiliary functions to build the augmentations.

Using these, we can build and test the grammar.

```
In [62]: parse and interpret("Sam likes ham", geah grammar, geah augmentations)
```

Semantics of ATIS queries

Now you're in a good position to understand and add augmentations to a more comprehensive grammar, say, one that parses ATIS queries and generates SQL queries.

In preparation for that, we need to load the ATIS data, both NL and SQL queries.

Loading and preprocessing the corpus

To simplify things a bit, we'll only consider ATIS queries whose question type (remember that from project segment 1?) is flight_id . We download training, development, and test splits for this subset of the ATIS corpus, including corresponding SQL queries.

Out[63]: 'data//train flightid (1).sql'

Let's take a look at the data: the NL queries are in .nl files, and the SQL queries are in .sql files.

```
In [64]: shell("head -1 data/dev_flightid.nl")
    shell("head -1 data/dev_flightid.sql")
```

what flights are available tomorrow from denver to philadelphia SELECT DISTINCT flight_1.flight_id FROM flight flight_1 , airport_service airport_service_1 , city city_1 , airport_service airport_service_2 , cit y city_2 , days days_1 , date_day date_day_1 WHERE flight_1.from_airport = airport_service_1.airport_code AND airport_service_1.city_code = city_1.city_code AND city_1.city_name = 'DENVER' AND (flight_1.to_airport = airport_service_2.airport_code AND airport_service_2.city_code = city_2.city_code AND city_2.city_name = 'PHILADELPHIA' AND flight_1.flight_days = days_1.days_code AND days_1.day_name = date_day_1.day_name AND date_day_1.year = 1991 AND date_day_1.month_number = 1 AND date_day_1.day_number = 20)

Corpus preprocessing

We'll use torchtext to process the data. We use two Field s: SRC for the questions, and TGT for the SQL queries. We'll use the tokenizer from project segment 3.

```
In [65]: | ## Tokenizer
         tokenizer = nltk.tokenize.RegexpTokenizer('\d+|st\.|[\w-]+|\$[\d\.]+|\S+')
         def tokenize(string):
           return tokenizer.tokenize(string.lower())
         ## Demonstrating the tokenizer
         ## Note especially the handling of `"11pm"` and hyphenated words.
         print(tokenize("Are there any first-class flights from St. Louis at 11pm fo
         ['are', 'there', 'any', 'first-class', 'flights', 'from', 'st.', 'louis',
         'at', '11', 'pm', 'for', 'less', 'than', '$3.50', '?']
In [66]: SRC = tt.data.Field(include lengths=True,
                                                           # include lengths
                                                           # batches will be max len
                             batch first=False,
                             tokenize=tokenize,
                                                           # use our tokenizer
         TGT = tt.data.Field(include_lengths=False,
                             batch first=False,
                                                           # batches will be max len
                             tokenize=lambda x: x.split(), # use split to tokenize
                             init_token="<bos>",
                                                           # prepend <bos>
                             eos token="<eos>")
                                                           # append <eos>
         fields = [('src', SRC), ('tgt', TGT)]
```

Note that we specified $batch_first=False$ (as in lab 4-4), so that the returned batched tensors would be of size $max_length x batch_size$, which facilitates seq2seq implementation.

Now, we load the data using torchtext. We use the TranslationDataset class here because our task is essentially a translation task: "translating" questions into the corresponding SQL queries. Therefore, we also refer to the questions as the *source* side (SRC) and the SQL queries as the *target* side (TGT).

```
In [67]: # Make splits for data
         train data, val data, test data = tt.datasets.TranslationDataset.splits(
             ('_flightid.nl', '_flightid.sql'), fields, path='./data/',
             train='train', validation='dev', test='test')
         MIN FREO = 3
         SRC.build_vocab(train_data.src, min_freq=MIN_FREQ)
         TGT.build vocab(train data.tgt, min freq=MIN FREQ)
         print (f"Size of English vocab: {len(SRC.vocab)}")
         print (f"Most common English words: {SRC.vocab.freqs.most common(10)}\n")
         print (f"Size of SQL vocab: {len(TGT.vocab)}")
         print (f"Most common SQL words: {TGT.vocab.freqs.most common(10)}\n")
         print (f"Index for start of sequence token: {TGT.vocab.stoi[TGT.init_token]
         print (f"Index for end of sequence token: {TGT.vocab.stoi[TGT.eos token]}")
         Size of English vocab: 421
         Most common English words: [('to', 3478), ('from', 3019), ('flights', 209
         4), ('the', 1550), ('on', 1230), ('me', 973), ('flight', 972), ('show', 8
         45), ('what', 833), ('boston', 813)]
         Size of SQL vocab: 392
         Most common SQL words: [('=', 38876), ('AND', 36564), (',', 22772), ('air
         port_service', 8314), ('city', 8313), ('(', 6432), (')', 6432), ('flight
         1.flight_id', 4536), ('flight', 4221), ('SELECT', 4178)]
         Index for start of sequence token: 2
         Index for end of sequence token: 3
```

Next, we batch our data to facilitate processing on a GPU. Batching is a bit tricky because the source and target will typically be of different lengths. Fortunately, torchtext allows us to pass in a sort_key function. By sorting on length, we can minimize the amount of padding on the source side, but since there is still some padding, we need to handle them with pack (padded sequence.html#torch.nn.and unpack

(https://pytorch.org/docs/stable/generated/torch.nn.utils.rnn.pad_packed_sequence.html) later on in the seq2seq part (as in lab 4-5).

Let's look at a single batch from one of these iterators.

```
In [69]: batch = next(iter(train_iter))
         train batch text, train batch text lengths = batch.src
         print (f"Size of text batch: {train_batch_text.shape}")
         print (f"Third sentence in batch: {train_batch_text[:, 2]}")
         print (f"Length of the third sentence in batch: {train_batch_text_lengths[2
         print (f"Converted back to string: { ' '.join([SRC.vocab.itos[i] for i in tr
         train batch sql = batch.tqt
         print (f"Size of sql batch: {train batch sql.shape}")
         print (f"Third SQL in batch: {train_batch_sql[:, 2]}")
         print (f"Converted back to string: { ' '.join([TGT.vocab.itos[i] for i in tr
         Size of text batch: torch.Size([8, 16])
         Third sentence in batch: tensor([ 9, 7, 4, 3, 64, 73, 2, 85])
         Length of the third sentence in batch: 8
         Converted back to string: show me flights from new york to miami
         Size of sql batch: torch.Size([72, 16])
         Third SQL in batch: tensor([ 2, 14, 31, 11,
                                                         13, 12,
                                                                    16,
                                                                               7,
         22,
               6,
                    8,
                        23,

```

Question: list all the flights that arrive at general mitchell internatio nal from various cities

SQL: SELECT DISTINCT flight_1.flight_id FROM flight flight_1 , airport ai rport_1 , airport_service airport_service_1 , city city_1 WHERE flight_1. to_airport = airport_1.airport_code AND airport_1.airport_code = 'MKE' AND flight_1.from_airport = airport_service_1.airport_code AND airport_service_1.city_code = city_1.city_code AND 1 = 1

Establishing a SQL database for evaluating ATIS queries

The output of our systems will be SQL queries. How should we determine if the generated queries are correct? We can't merely compare against the gold SQL queries, since there are many ways to implement a SQL query that answers any given NL query.

Instead, we will execute the queries – both the predicted SQL query and the gold SQL query – on an actual database, and verify that the returned responses are the same. For that purpose, we need a SQL database server to use. We'll set one up here, using the Python_sqlite3_module (https://docs.python.org/3.8/library/sglite3.html).

```
In [71]: @func_set_timeout(TIMEOUT)
    def execute_sql(sql):
        conn = sqlite3.connect('data/atis_sqlite.db')  # establish the DB based o
        c = conn.cursor()  # build a "cursor"
        c.execute(sql)
        results = list(c.fetchall())
        c.close()
        conn.close()
        return results
```

To run a query, we use the cursor's execute function, and retrieve the results with fetchall. Let's get all the flights that arrive at General Mitchell International – the query train_sql_1 above. There's a lot, so we'll just print out the first few.

```
Executing: SELECT DISTINCT flight_1.flight_id FROM flight flight_1 , airp
ort airport_1 , airport_service airport_service_1 , city city_1 WHERE fli
ght_1.to_airport = airport_1.airport_code AND airport_1.airport_code = 'M
KE' AND flight_1.from_airport = airport_service_1.airport_code AND airpor
t_service_1.city_code = city_1.city_code AND 1 = 1

Result: 534 entries starting with

[(107929,), (107930,), (107931,), (107932,), (107933,), (107934,), (107935,), (107936,), (107937,), (107938,)]
```

For your reference, the SQL database we are using has a database schema described at https://github.com/jkkummerfeld/text2sql-data/blob/master/data/atis-schema.csv (https://github.com/jkkummerfeld/text2sql-data/blob/master/data/atis-schema.csv), and is consistent with the SQL queries provided in the various https://github.com/jkkummerfeld/text2sql-data/blob/master/data/atis-schema.csv), and is consistent with the SQL queries provided in the various https://github.com/jkkummerfeld/text2sql-data/blob/master/data/atis-schema.csv), and is

Rule-based parsing and interpretation of ATIS queries

First, you will implement a rule-based semantic parser using a grammar like the one you completed in the third project segment. We've placed an initial grammar in the file <code>data/grammar</code>. In addition to the helper functions defined above (<code>constant</code>, <code>first</code>, etc.), it makes use of some other simple functions. We've included those below, but you can (and almost certainly should) augment this set with others that you define as you build out the full set of augmentations.

```
In [93]: def upper(term):
           return '"' + term.upper() + '"'
         def weekday(day):
           return f"flight.flight days IN (SELECT days.days code FROM days WHERE day
         def month_name(month):
           return {'JANUARY' : 1,
                   'FEBRUARY' : 2,
                   'MARCH' : 3,
                   'APRIL' : 4,
                   'MAY' : 5,
                   'JUNE' : 6,
                   'JULY' : 7,
                   'AUGUST' : 8,
                   'SEPTEMBER' : 9,
                    'OCTOBER': 10,
                   'NOVEMBER': 11,
                    'DECEMBER' : 12}[month.upper()]
         def airports from airport name(airport name):
           return f"(SELECT airport.airport code FROM airport WHERE airport.airport
         def airports from city(city):
           return f"""
             (SELECT airport service.airport code FROM airport service WHERE airport
               (SELECT city.city code FROM city WHERE city.city name = {upper(city)}
         def null condition(*args, **kwargs):
           return 1
         def depart around(time):
           return f"""
             flight.departure_time >= {add_delta(miltime(time), -15).strftime('%H%M'
             AND flight.departure time <= {add delta(miltime(time), 15).strftime('%H
             """.strip()
         def add delta(tme, delta):
             # transform to a full datetime first
             return (datetime.datetime.combine(datetime.date.today(), tme) +
                     datetime.timedelta(minutes=delta)).time()
         def miltime(minutes):
           return datetime.time(hour=int(minutes/100), minute=(minutes % 100))
```

We can build a parser with the augmented grammar:

We'll define a function to return a parse tree for a string according to the ATIS grammar (if available).

```
In [95]: def parse_tree(sentence):
    """Parse a sentence and return the parse tree, or None if failure."""
    try:
        parses = list(atis_parser.parse(tokenize(sentence)))
        if len(parses) == 0:
            return None
        else:
            return parses[0]
        except:
            return None
```

We can check the overall coverage of this grammar on the training set by using the parse_tree function to determine if a parse is available. The grammar that we provide should get about a 40% coverage of the training set.

```
100% | 3651/3651 [00:12<00:00, 298.65it/s]
```

Parsed 1609 of 3651 (44.07%)

Goal 1: Construct SQL queries from a parse tree and evaluate the results

It's time to turn to the first major part of this project segment, implementing a rule-based semantic parsing system to answer flight-ID-type ATIS queries.

Recall that in rule-based semantic parsing, each syntactic rule is associated with a semantic composition rule. The grammar we've provided has semantic augmentations for some of the low-level phrases – cities, airports, times, airlines – but not the higher level syntactic types. You'll be adding those.

In the ATIS grammar that we provide, as with the earlier toy grammars, the augmentation for a rule with n nonterminals and m terminals on the right-hand side is assumed to be called with n positional arguments (the values for the corresponding children). The <code>interpret</code> function you've already defined should therefore work well with this grammar.

Let's run through one way that a semantic derivation might proceed, for the sample query "flights to boston":

```
In [97]: sample query = "flights to boston"
         print(tokenize(sample query))
         sample_tree = parse_tree(sample_query)
         sample_tree.pretty_print()
          ['flights', 'to', 'boston']
                      NP_FLIGHT
                      NOM FLIGHT
                       N_{\rm FLIGHT}
                                     PP
                                  PP PLACE
                                             N PLACE
            N FLIGHT
         TERM FLIGHT
                       P PLACE
                                            TERM PLACE
            flights
                                              boston
                           to
```

Given a sentence, we first construct its parse tree using the syntactic rules, then compose the corresponding semantic rules bottom-up, until eventually we arrive at the root node with a finished SQL statement. For this query, we will go through what the possible meaning representations for the subconstituents of "flights to boston" might be. But this is just one way of doing things; other ways are possible, and you should feel free to experiment.

Working from bottom up:

1. The TERM_PLACE phrase "boston" uses the composition function template constant(airports_from_city(' '.join(_RHS))), which will be instantiated as constant(airports_from_city(' '.join(['boston']))) (recall that _RHS is replaced by the right-hand side of the rule). The meaning of TERM_PLACE will be the SQL snippet

```
SELECT airport_service.airport_code
FROM airport_service
WHERE airport_service.city_code IN
  (SELECT city.city_code
  FROM city
  WHERE city.city_name = "BOSTON")
```

(This query generates a list of all of the airports in Boston.)

2. The N_PLACE phrase "boston" can have the same meaning as the TERM_PLACE.

- 3. The P_PLACE phrase "to" might be associated with a function that maps a SQL query for a list of airports to a SQL condition that holds of flights that go to one of those airports, i.e., flight.to airport IN (...).
- 4. The PP_PLACE phrase "to boston" might apply the P_PLACE meaning to the TERM_PLACE meaning, thus generating a SQL condition that holds of flights that go to one of the Boston airports:

```
flight.to_airport IN
  (SELECT airport_service.airport_code
  FROM airport_service
  WHERE airport_service.city_code IN
       (SELECT city.city_code
       FROM city
       WHERE city.city_name = "BOSTON")
```

- 5. The PP phrase "to Boston" can again get its meaning from the PP_PLACE.
- 6. The TERM_FLIGHT phrase "flights" might also return a condition on flights, this time the "null condition", represented by the SQL truth value 1. Ditto for the N_FLIGHT phrase "flights".
- 7. The N_FLIGHT phrase "flights to boston" can conjoin the two conditions, yielding the SQL condition

```
flight.to_airport IN
  (SELECT airport_service.airport_code
  FROM airport_service
  WHERE airport_service.city_code IN
        (SELECT city.city_code
        FROM city
        WHERE city.city_name = "BOSTON")
AND 1
```

which can be inherited by the NOM_FLIGHT and NP_FLIGHT phrases.

8. The s phrase "flights to boston" can use the condition provided by the NP_FLIGHT phrase to select all flights satisfying the condition with a SQL query like

```
SELECT DISTINCT flight.flight_id
FROM flight
WHERE flight.to_airport IN
    (SELECT airport_service.airport_code
    FROM airport_service
    WHERE airport_service.city_code IN
         (SELECT city.city_code
          FROM city
          WHERE city.city_name = "BOSTON")
AND 1
```

This SQL query is then taken to be a representation of the meaning for the NL query "flights to boston", and can be executed against the ATIS database to retrieve the requested flights.

Now, it's your turn to add augmentations to data/grammar to make this example work. The augmentations that we have provided for the grammar make use of a set of auxiliary functions that

we defined above. You should feel free to add your own auxiliary functions that you make use of in the grammar.

```
In [98]: #TODO: add augmentations to `data/grammar` to make this example work
    atis_grammar, atis_augmentations = xform.read_augmented_grammar('data/gramm
    atis_parser = nltk.parse.BottomUpChartParser(atis_grammar)
    predicted_sql = interpret(sample_tree, atis_augmentations)
    print("Predicted SQL:\n\n", predicted_sql, "\n")

Predicted SQL:

SELECT DISTINCT flight.flight_id FROM flight WHERE 1 AND flight.to_airpo
    rt IN
        (SELECT airport_service.airport_code FROM airport_service WHERE airpo
    rt_service.city_code IN
        (SELECT city.city_code FROM city WHERE city.city_name = "BOSTON"))
```

Verification on some examples

With a rule-based semantic parsing system, we can generate SQL queries given questions, and then execute those queries on a SQL database to answer the given questions. To evaluate the performance of the system, we compare the returned results against the results of executing the ground truth queries.

We provide a function verify to compare the results from our generated SQL to the ground truth SQL. It should be useful for testing individual queries.

```
In [99]: def verify(predicted_sql, gold_sql, silent=True):
           Compare the correctness of the generated SQL by executing on the
           ATIS database and comparing the returned results.
           Arguments:
               predicted sql: the predicted SQL query
               gold sql: the reference SQL query to compare against
               silent: print outputs or not
           Returns: True if the returned results are the same, otherwise False
           # Execute predicted SOL
             predicted result = execute sql(predicted sql)
           except BaseException as e:
             if not silent:
               print(f"predicted sql exec failed: {e}")
             return False
           if not silent:
             print("Predicted DB result:\n\n", predicted_result[:10], "\n")
           # Execute gold SQL
           try:
             gold_result = execute_sql(gold_sql)
           except BaseException as e:
             if not silent:
               print(f"gold sql exec failed: {e}")
             return False
           if not silent:
             print("Gold DB result:\n\n", gold result[:10], "\n")
           # Verify correctness
           if gold result == predicted result:
             return True
```

Let's try this methodology on a simple example: "flights from phoenix to milwaukee". we provide it along with the gold SQL query.

```
In [100]: def rule_based_trial(sentence, gold_sql):
    print("Sentence: ", sentence, "\n")
    tree = parse_tree(sentence)
    print("Parse:\n\n")
    tree.pretty_print()

    predicted_sql = interpret(tree, atis_augmentations)
    print("Predicted SQL:\n\n", predicted_sql, "\n")

    if verify(predicted_sql, gold_sql, silent=False):
        print ('Correct!')
    else:
        print ('Incorrect!')
```

```
In [101]: # Run this cell to reload augmentations after you make changes to `data/gra
    atis_grammar, atis_augmentations = xform.read_augmented_grammar('data/gramm
    atis_parser = nltk.parse.BottomUpChartParser(atis_grammar)
```

```
In [102]: #TODO: add augmentations to `data/grammar` to make this example work
          # Example 1
          example_1 = 'flights from phoenix to milwaukee'
          gold_sql_1 = """
            SELECT DISTINCT flight_1.flight_id
            FROM flight flight_1 ,
                 airport_service airport_service_1 ,
                 city city 1 ,
                 airport service airport service 2 ,
                 city city_2
            WHERE flight 1.from airport = airport service 1.airport code
                  AND airport service 1.city code = city 1.city code
                  AND city_1.city_name = 'PHOENIX'
                  AND flight 1.to airport = airport service 2.airport code
                  AND airport_service_2.city_code = city_2.city_code
                  AND city 2.city name = 'MILWAUKEE'
            0.00
          rule_based_trial(example_1, gold_sql_1)
```

Sentence: flights from phoenix to milwaukee

Parse:

Predicted SQL:

SELECT DISTINCT flight_flight_id FROM flight WHERE 1 AND flight.from_a irport IN

(SELECT airport_service.airport_code FROM airport_service WHERE air port_service.city_code IN

(SELECT city.city_code FROM city WHERE city.city_name = "PHOENI
X"))

AND flight.to airport IN

(SELECT airport_service.airport_code FROM airport_service WHERE air port_service.city_code IN

(SELECT city.city_code FROM city WHERE city.city_name = "MILWAUKE

```
E"))

Predicted DB result:

[(108086,), (108087,), (301763,), (301764,), (301765,), (301766,), (302323,), (304881,), (310619,), (310620,)]

Gold DB result:

[(108086,), (108087,), (301763,), (301764,), (301765,), (301766,), (302323,), (304881,), (310619,), (310620,)]

Correct!
```

To make development faster, we recommend starting with a few examples before running the full evaluation script. We've taken some examples from the ATIS dataset including the gold SQL queries that they provided. Of course, yours (and those of the project segment solution set) may differ.

```
In [103]: #TODO: add augmentations to `data/grammar` to make this example work
                                    # Example 2
                                    example_2 = 'i would like a united flight'
                                    gold_sql_2 = """
                                           SELECT DISTINCT flight_1.flight_id

Systematic evaluation on a test set

We can perform a more systematic evaluation by checking the accuracy of the queries on an entire test set for which we have gold queries. The evaluate function below does just this, calculating precision, recall, and F1 metrics for the test set. It takes as argument a "predictor" function, which

maps token sequences to predicted SQL queries. We've provided a predictor function for the rule-based model in the next cell (and a predictor for the seq2seq system below when we get to that system).

The rule-based system does not generate predictions for all queries; many queries won't parse. The precision and recall metrics take this into account in measuring the efficacy of the method. The recall metric captures what proportion of *all of the test examples* for which the system generates a correct query. The precision metric captures what proportion of *all of the test examples for which a prediction is generated* for which the system generates a correct query. (Recall that F1 is just the geometric mean of precision and recall.)

Once you've made some progress on adding augmentations to the grammar, you can evaluate your progress by seeing if the precision and recall have improved. For reference, the solution code achieves precision of about 71% and recall of about 27% for an F1 of 40%.

```

End-to-End Seq2Seq Model

In this part, you will implement a seq2seq model **with attention mechanism** to directly learn the translation from NL query to SQL. You might find labs 4-4 and 4-5 particularly helpful, as the primary difference here is that we are using a different dataset.

Note: We recommend using GPUs to train the model in this part (one way to get GPUs is to use <u>Google Colab (https://colab.research.google.com)</u> and clicking Menu -> Runtime -> Change runtime type -> GPU), as we need to use a very large model to solve the task well. For development we recommend starting with a smaller model and training for only 1 epoch.

Goal 2: Implement a seq2seq model (with attention)

In lab 4-5, you implemented a neural encoder-decoder model with attention. That model was used to convert English number phrases to numbers, but one of the biggest advantages of neural models is that we can easily apply them to different tasks (such as machine translation and document summarization) by using different training datasets.

Implement the class AttnEncoderDecoder to convert natural language queries into SQL statements. You may find that you can reuse most of the code you wrote for lab 4-5. A reasonable way to proceed is to implement the following methods:

Model

- 1. __init__ : an initializer where you create network modules.
- 2. forward: given source word ids of size (max_src_len, batch_size), source lengths of size (batch_size) and decoder input target word ids (max_tgt_len, batch_size), returns logits (max_tgt_len, batch_size, V_tgt). For better modularity you might want to implement it by implementing two functions forward_encoder and forward_decoder.

Optimization

- 3. train_all: compute loss on training data, compute gradients, and update model parameters to minimize the loss.
- 4. evaluate_ppl : evaluate the current model's perplexity on a given dataset iterator, we use the perplexity value on the validation set to select the best model.

Decoding

5. predict: Generates the target sequence given a list of source tokens using beam search decoding. Note that here you can assume the batch size to be 1 for simplicity.

```
In [116]: def attention(batched Q, batched K, batched V, mask=None):
            Performs the attention operation and returns the attention matrix
            `batched_A` and the context matrix `batched_C` using queries
            `batched_Q`, keys `batched_K`, and values `batched_V`.
            Arguments:
                batched Q: (q len, bsz, D)
                batched_K: (k_len, bsz, D)
                batched_V: (k_len, bsz, D)
                mask: (bsz, q len, k len). An optional boolean mask *disallowing*
                      attentions where the mask value is *`False`*.
            Returns:
                batched A: the normalized attention scores (bsz, g len, k len)
                batched_C: a tensor of size (q_len, bsz, D).
            # Check sizes

Out[346]: Ellipsis

We provide the recommended hyperparameters for the final model in the script below, but you are free to tune the hyperparameters or change any part of the provided code.

For quick debugging, we recommend starting with smaller models (by using a very small hidden_size), and only a single epoch. If the model runs smoothly, then you can train the full model on GPUs.

```
In [347]: EPOCHS = 1 # epochs; we recommend starting with a smaller number like 1
    LEARNING_RATE = 1e-4 # learning rate

# Instantiate and train classifier
model = AttnEncoderDecoder(SRC, TGT,
    hidden_size = 100,
    layers = 1,
    ).to(device)

model.train_all(train_iter, val_iter, epochs=EPOCHS, learning_rate=LEARNING
model.load_state_dict(model.best_model)

# Evaluate model performance, the expected value should be < 1.2
print (f'Validation perplexity: {model.evaluate_ppl(val_iter):.3f}')</pre>
```

```
100% | 229/229 [00:49<00:00, 4.62it/s]
```

Epoch: 0 Training Perplexity: 105.0489 Validation Perplexity: 26.4906 Validation perplexity: 26.491

With a trained model, we can convert questions to SQL statements. We recommend making sure

that the model can generate at least reasonable results on the examples from before, before evaluating on the full test set.

KeyboardInterrupt:

Goal 3: Implement a seq2seq model (with cross attention and self attention)

In the previous section, you have implemented a seq2seq model with attention. The attention mechanism used in that section is usually referred to as "cross-attention", as at each decoding step, the decoder attends to encoder outputs, enabling a dynamic view on the encoder side as decoding proceeds.

Similarly, we can have a dynamic view on the decoder side as well as decoding proceeds, i.e., the decoder attends to decoder outputs at previous steps. This is called "self attention", and has been found very useful in modern neural architectures such as transformers.

Augment the seq2seq model you implemented before with a decoder self-attention mechanism as class AttnEncoderDecoder2. A model diagram can be found below:

At each decoding step, the decoder LSTM first produces an output state o_t , then it attends to all previous output states o_1, \ldots, o_{t-1} (decoder self-attention). You need to special case the first decoding step to not perform self-attention, as there are no previous decoder states. The attention result is added to o_t itself and the sum is used as q_t to attend to the encoder side (encoder-decoder cross-attention). The rest of the model is the same as encoder-decoder with attention.

```
In [358]: #TODO - implement the `AttnEncoderDecoder2` class.

Discussion

Goal 4: Compare the pros and cons of rule-based and neural approaches.

Compare the pros and cons of the rule-based approach and the neural approaches with relevant examples from your experiments above. Concerning the accuracy, which approach would you choose to be used in a product? Explain.

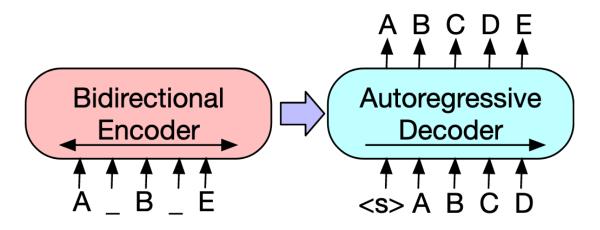

The main difference that exists between the rule-based approach and the neural approach is that the neural approach will generate its own rules depending on the data that is fed into it whereas the rules must be humanly defind for the rule-based approach. A pro of the rule-based approach is that the changes that occur in performance when a rule is changed are very opaque and understandable to humans, compared to a change in performance for a neural approach being very black box-like. Additionally, the aspects of the dataset that are focused on can be better defined by a rule-based approach whereas it is difficult to specify the scope of a neural approach as it is usually broader. However, a pro of the neural approach is that the methods are generalizable to many problems whereas the rule-based approach is only applicable to the specific problem or dataset that the rules were written for. For the ATIS dataset, we wrote rules but they wouldn't be able to generalize to another dataset whereas the neural approach is much more generalizable. Additionally, a pro of rule-based is that the outputs are much quicker than that of the neural approach, as evidenced by the large amount of time it took to train the neural approach. Given the accuracy, I would choose the neural approach over the rule-based approach. The neural approach can always improve through additional layers, higher hidden_size, and additional epochs without changing the data or additional time put in whereas the rule-based approach would take additional time to improve in any way. Thus, the upside of the neural approach is higher than that of the rulebased approach, which is why I would choose the neural approach.

(Optional) Goal 5: Use state-of-the-art pretrained transformers

The most recent breakthrough in natural-language processing stems from the use of pretrained transformer models. For example, you might have heard of pretrained transformers such as GPT-3 (https://arxiv.org/abs/2005.14165) and BERT (https://arxiv.org/abs/1810.04805). (BERT is already used in <a href="https://searchengineland.com/google-bert-used-on-almost-every-english-query-342193).) These models are usually trained on vast amounts of text data using variants of language modeling objectives, and researchers have found that finetuning them on downstream tasks usually results in better performance as compared to training a model from scratch.

In the previous part, you implemented an LSTM-based sequence-to-sequence approach. To "upgrade" the model to be a state-of-the-art pretrained transformer only requires minor modifications.

The pretrained model that we will use is <u>BART (https://arxiv.org/abs/1910.13461)</u>, which uses a bidirectional transformer encoder and a unidirectional transformer decoder, as illustrated in the below diagram (image courtesy https://arxiv.org/pdf/1910.13461):

We can see that this model is strikingly similar to the LSTM-based encoder-decoder model we've been using. The only difference is that they use transformers instead of LSTMs. Therefore, we only need to change the modeling parts of the code, as we will see later.

First, we download and load the pretrained BART model from the transformers (https://github.com/huggingface/transformers) package by Huggingface. Note that we also need to use the "tokenizer" of BART, which is actually a combination of a tokenizer and a mapping from strings to word ids.

```
In [ ]: pretrained_bart = BartForConditionalGeneration.from_pretrained('facebook/babart_tokenizer = BartTokenizer.from_pretrained('facebook/bart_base')
```

Below we demonstrate how to use BART's tokenizer to convert a sentence to a list of word ids, and vice versa.

```
In []: # BART uses a predefined "tokenizer", which directly maps a sentence
# to a list of ids
def bart_tokenize(string):
    return bart_tokenizer(string)['input_ids'][:1024] # BART model can proces

def bart_detokenize(token_ids):
    return bart_tokenizer.decode(token_ids, skip_special_tokens=True)

## Demonstrating the tokenizer
question = 'Are there any first-class flights from St. Louis at 11pm for le

tokenized_question = bart_tokenize(question)
print('tokenized:', tokenized_question)

detokenized_question = bart_detokenize(tokenized_question)
print('detokenized:', detokenized_question)
```

We need to reprocess the data using our new tokenizer. Note that here we set <code>batch_first</code> to <code>True</code>, since that's the expected input shape of the transformers package.

```
In [ ]: SRC_BART = tt.data.Field(include_lengths=True, # include lengths
                                 batch first=True, # batches will be batch si
                                 tokenize=bart_tokenize, # use bart tokenizer
                                 use vocab=False, # bart tokenizer already c
                                 pad_token=bart_tokenizer.pad_token_id
        TGT BART = tt.data.Field(include lengths=False,
                                batch first=True, # batches will be batch si
                                 tokenize=bart_tokenize, # use bart tokenizer
                                 use vocab=False,
                                                        # bart tokenizer already c
                                 pad token=bart tokenizer.pad token id
        fields_bart = [('src', SRC_BART), ('tgt', TGT_BART)]
        # Make splits for data
        train_data_bart, val_data_bart, test_data_bart = tt.datasets.TranslationDat
            ('_flightid.nl', '_flightid.sql'), fields_bart, path='./data/',
            train='train', validation='dev', test='test')
        BATCH SIZE = 1 # batch size for training/validation
        TEST BATCH SIZE = 1 # batch size for test, we use 1 to make beam search imp
        train iter_bart, val iter_bart = tt.data.BucketIterator.splits((train_data_
                                                            batch size=BATCH SIZE,
                                                            device=device,
                                                            repeat=False,
                                                            sort key=lambda x: len
                                                            sort within batch=True
        test iter bart = tt.data.BucketIterator(test data bart,
                                          batch size=1,
                                           device=device,
                                           repeat=False,
                                           sort=False,
                                           train=False)
```

Let's take a look at the batch. Note that the shape of the batch is $batch_size x max_len$, instead of $max_len x batch_size$ as in the previous part.

```
In [ ]: batch = next(iter(train_iter_bart))
    train_batch_text, train_batch_text_lengths = batch.src
    print (f"Size of text batch: {train_batch_text.shape}")
    print (f"First sentence in batch: {train_batch_text[0]}")
    print (f"Length of the third sentence in batch: {train_batch_text_lengths[0]
    print (f"Converted back to string: {bart_detokenize(train_batch_text[0])}")

    train_batch_sql = batch.tgt
    print (f"Size of sql batch: {train_batch_sql.shape}")
    print (f"First sql in batch: {train_batch_sql[0]}")
    print (f"Converted back to string: {bart_detokenize(train_batch_sql[0])}")
```

Now we are ready to implement the BART-based approach for the text-to-SQL conversion problem. In the below BART class, we have provided the constructer __init__ , the forward function, and the predict function. Your job is to implement the main optimization train all , and evaluate ppl for evaluating validation perplexity for model selection.

Hint: you can use almost the same train_all and evaluate_ppl function you implemented before, but here a major difference is that due to setting batch_first=True, the batched source/target tensors are of size batch_size x max_len, as opposed to max_len x batch_size in the LSTM-based approach, and you need to make changes in train_all and evaluate_ppl accordingly.

```
In [ ]: #TODO - finish implementing the `BART` class.
        class BART(nn.Module):
          def __init__(self, tokenizer, pretrained_bart):
            Initializer. Creates network modules and loss function.
            Arguments:
                tokenizer: BART tokenizer
                pretrained bart: pretrained BART
            super(BART, self).__init__()
            self.V_tgt = len(tokenizer)
            # Get special word ids
            self.padding_id_tgt = tokenizer.pad_token_id
            # Create essential modules
            self.bart = pretrained bart
            # Create loss function
            self.loss function = nn.CrossEntropyLoss(reduction="sum",
                                                      ignore index=self.padding id t
          def forward(self, src, src lengths, tgt in):
            Performs forward computation, returns logits.
            Arguments:
                src: src batch of size (batch size, max src len)
                src lengths: src lengths of size (batch size)
                tgt in: a tensor of size (tgt len, bsz)
            . . .
            # BART assumes inputs to be batch-first
            # This single function is forwarding both encoder and decoder (w/ cross
            # using `input ids` as encoder inputs, and `decoder input ids`
            # as decoder inputs.
            logits = self.bart(input ids=src,
                               decoder input ids=tgt in,
                               use cache=False
                               ).logits
            return logits
          def evaluate ppl(self, iterator):
            """Returns the model's perplexity on a given dataset `iterator`."""
            #TODO - implement this function
            ppl = ...
            return ppl
          def train all(self, train iter, val iter, epochs=10, learning rate=0.001)
            """Train the model."""
            #TODO - implement this function
          def predict(self, tokens, K=1, max T=400):
            Generates the target sequence given the source sequence using beam sear
```

```
Note that for simplicity, we only use batch size 1.
Arguments:
    tokens: a list of strings, the source sentence.
    max T: at most proceed this many steps of decoding
Returns:
    a string of the generated target sentence.
string = ' '.join(tokens) # first convert to a string
# Tokenize and map to a list of word ids
inputs = torch.LongTensor(bart tokenize(string)).to(device).view(1, -1)
# The `transformers` package provides built-in beam search support
prediction = self.bart.generate(inputs,
                                num beams=K,
                                max_length=max_T,
                                early stopping=True,
                                no_repeat_ngram_size=0,
                                decoder start token id=0,
                                use_cache=True)[0]
```

return bart_detokenize(prediction)

The code below will kick off training, and evaluate the validation perplexity. You should expect to see a value very close to 1.

As before, make sure that your model is making reasonable predictions on a few examples before evaluating on the entire test set.

```
In [ ]: def bart_trial(sentence, gold_sql):
    print("Sentence: ", sentence, "\n")
    tokens = tokenize(sentence)

predicted_sql = bart_model.predict(tokens, K=1, max_T=300)
    print("Predicted SQL:\n\n", predicted_sql, "\n")

if verify(predicted_sql, gold_sql, silent=False):
    print ('Correct!')
    else:
        print ('Incorrect!')
```

```
In [ ]: bart_trial(example_1, gold_sql_1)
```

```
In [ ]: bart_trial(example_2, gold_sql_2)
In [ ]: bart_trial(example_3, gold_sql_3)
In [ ]: bart_trial(example_4, gold_sql_4)
In [ ]: bart_trial(example_5, gold_sql_5)
In [ ]: bart_trial(example_6, gold_sql_6b)
In [ ]: bart_trial(example_7, gold_sql_7b)
In [ ]: bart_trial(example_8, gold_sql_8)
```

Evaluation

The code below will evaluate on the entire test set. You should expect to see precision/recall/F1 greater than 40%.

```
In [ ]: def seq2seq_predictor_bart(tokens):
    prediction = bart_model.predict(tokens, K=4, max_T=400)
    return prediction

In [ ]: precision, recall, f1 = evaluate(seq2seq_predictor_bart, test_iter.dataset,
```

Debrief

Question: We're interested in any thoughts you have about this project segment so that we can improve it for later years, and to inform later segments for this year. Please list any issues that arose or comments you have to improve the project segment. Useful things to comment on might include the following:

- Was the project segment clear or unclear? Which portions?
- Were the readings appropriate background for the project segment?
- Are there additions or changes you think would make the project segment better?

but you should comment on whatever aspects you found especially positive or negative.

I had a lot more trouble with this project segment than others. I was able to get Goal 1 working well and filled out the grammar completely. However, I wasn't able to get my predict function working completely correctly for Goal 2 and Goal 3, which led to me being unable to check whether my grammar was correct and it took too long to run the 50 epochs so I wasn't able to check my

perplexity either. The high perplexity value was present for 1 epoch, hidden size = 100 and layers = 1. I ran for 10 epochs which led to a much lower perplexity but overrode the values and didn't have time to run it again.

Additionally, I also wasn't able to get the self-attention working completely correctly. I attempted an implementation of it by adding in the prev_decoder_states functionality in order to get the self-attention to compute but ran into some issues that I wasn't able to solve because of time.

Overall, I think I was close to correct on my implementation for the predict method and the selfattention but wasn't able to fix it completely because of time constraints.

I think that I was very overwhelmed during this finals period and wasn't able to put forth my best work, which I apologize for. Hopefully I am able to get some credit for the time that I put in.

I think the readings and lab segments were appropriate background for the project segment.

I thought it was pretty difficult to finish out all of the grammar semantic additions and some more guidance on that would have been nice.

Instructions for submission of the project segment

This project segment should be submitted to Gradescope at http://go.cs187.info/project4-submit-code) and http://go.cs187.info/project4-submit-pdf), which will be made available some time before the due date.

Project segment notebooks are manually graded, not autograded using otter as labs are. (Otter is used within project segment notebooks to synchronize distribution and solution code however.) **We will not run your notebook before grading it.** Instead, we ask that you submit the already freshly run notebook. The best method is to "restart kernel and run all cells", allowing time for all cells to be run to completion. You should submit your code to Gradescope at the code submission assignment at http://go.cs187.info/project4-submit-code (http://go.c

We also request that you **submit a PDF of the freshly run notebook**. The simplest method is to use "Export notebook to PDF", which will render the notebook to PDF via LaTeX. If that doesn't work, the method that seems to be most reliable is to export the notebook as HTML (if you are using Jupyter Notebook, you can do so using File -> Print Preview), open the HTML in a browser, and print it to a file. Then make sure to add the file to your git commit. Please name the file the same name as this notebook, but with a .pdf extension. (Conveniently, the methods just described will use that name by default.) You can then perform a git commit and push and submit the commit to Gradescope at http://go.cs187.info/project4-submit-pdf(http://go.cs187.info/project4-submit-pdf).

End of project segment 4 {-}
